1. Introduction

ARCADIS US, Inc. (ARCADIS) has developed this definitive screening-level ecological risk assessment (SLERA) on behalf of CSX Transportation (CSXT) for the portions of Clear Creek (the Study Area) associated with the former Indiana Creosoting Company (ICC) facility (hereafter referred to as the "Site") located at 240 Country Club Drive in Bloomington, Monroe County, Indiana (Figure 1). The purpose of this SLERA is to assist with closure activities under the Indiana Department of Environmental Management's (IDEM) Voluntary Remediation Program (VRP) at the Site. This report documents data collected for the SLERA from 1991 through 2011.

1.1 Background Information

As an initial step in this process, a baseline ecological assessment (BEA), as defined by IDEM (1996), was conducted by ARCADIS in 1999 (ARCADIS 2003) for the western portion of what is presently the Site. The BEA identified Clear Creek as an ecologically susceptible area, requiring evaluation of potential risks.

Four SLERA investigation events have been conducted for the portions of Clear Creek associated with the Site in April 1991, August and October 2003 and finally in September 2010. Sediment, surface water, and porewater samples were collected and analyzed for the constituents of concern (COCs) at the Site which included dense non-aqueous phase liquid (DNAPL; creosote), selected semi volatile organic compounds (SVOCs: phenols, phthalates, and priority pollutant and alkylated polycyclic aromatic hydrocarbons (PAHs)), and selected volatile organic compounds (VOCs: benzene, toluene, ethylbenzene, and xylene [BTEX]), and metals (total, dissolved, and as simultaneously extracted metals (SEM) and acid volatile sulfide (AVS).

A preliminary SLERA was conducted in 2004 based on the 1991 and 2003 data. The preliminary SLERA concluded that the only COCs that may cause potential risk to ecological receptors in Clear Creek are PAHs. Based in part on the results of the preliminary SLERA and intermittent presence of DNAPL globules on the creek bottom in the area directly adjacent east of the former operations area, a mitigation measure in the form of a creek liner was installed in Summer-Fall 2007 along an approximate 170 foot section of Clear Creek within the northern tract of the Site. The preliminary SLERA results are included herein as part of this definitive SLERA.

In September 2010, ARCADIS collected sediment and surface water samples to assess the current conditions of Clear Creek and to confirm the effectiveness of the mitigation measures taken in 2007. Subsequently, a definitive SLERA was conducted to refine the results of the preliminary SLERA and in particular to assess risk to aquatic organisms from organics in Clear Creek. The definitive SLERA provides a baseline evaluation of the nature and geographical extent of the possible ecological risks remaining, based on current knowledge of environmental conditions, COCs, and ecological receptors in the Study Area using the data obtained in 2010.

1.2 Purpose and Objectives

A SLERA is designed to identify constituents of potential ecological concern (COPECs) and areas that merit further investigation. In this evaluation, constituents in sediment and surface water from the Study Area within Clear Creek are evaluated based on comparisons to ecological screening values (ESVs) and other relevant scientific information.

The specific objectives of this SLERA are to:

- identify potentially exposed receptors of interest (ROIs) at the Study Area and potentially complete exposure pathways by which ROIs may be exposed to constituents in environmental media;
- identify constituents in environmental media (sediment and surface water) at the Study Area that do not pose an ecological risk;
- identify COPECs that might pose a potential risk of adverse effects to ecological receptors at the Study Area; and
- evaluate the appropriate remedy or remedies for the Study Area based on existing information, if there is a potential for risk of adverse effects to ecological receptors.

1.3 Conceptual Approach

This SLERA follows relevant U.S. Environmental Protection Agency (U.S. EPA) guidance, including:

- Framework for ecological risk assessment (U.S. EPA 1992);
- Ecological Risk Assessment Guidance for Superfund: *Process for Designing and Conducting Ecological Risk Assessments* (U.S. EPA 1997);

- Guidelines for ecological risk assessment (U.S. EPA1998); and
- Ecological Risk Assessment and Risk Management Principles for Superfund Sites (U.S. EPA 1999).

The conceptual approach to the SLERA involves: 1) defining the system to be studied, 2) identifying the study's goals and objectives, 3) providing the details of the analysis, and 4) describing conclusions of the analysis. This approach is consistent with the conceptual framework for ecological risk assessment developed by the U.S. EPA (U.S. EPA 1992), which includes three major components: problem formulation, analysis (exposure characterization and effects characterization), and risk characterization. The SLERA is organized according to these three components, as follows.

- Problem formulation is a process to define the specific issues addressed in the SLERA. Problem formulation describes: 1) ecological resources at the Study Area; 2) representative ROIs, constituent characterization methods, and complete exposure pathways; 3) a conceptual site model (CSM) that establishes the exposure pathways and defines the relationships among endpoints; and 4) assessment and measurement endpoints specifying the goals of the SLERA.
- Analysis includes: 1) exposure characterization, which quantifies the measured concentrations of constituents in environmental media; and 2) effects characterization, which identifies the ESVs to be used in the assessment.
- Risk characterization is the integration of the exposure and effects information to identify COPECs. Uncertainties in the SLERA process are also discussed.

Collectively, these components of the SLERA are intended to provide a scientifically sound basis for further investigation to support a baseline ecological risk assessment (BERA), if necessary. This risk assessment process will evaluate the nature and spatial extent of possible ecological effects based on current environmental conditions at the Site.

2. Problem Formulation

Problem formulation is a process for generating and evaluating preliminary hypotheses about why ecological effects have occurred, or may occur, from human activities. In problem formulation, the purpose for the SLERA is articulated, the problem is defined, and a plan for analyzing and characterizing risk is determined. The following discussion describes the Site and ecological setting and identifies ROIs, constituent characterization methods, exposure pathways, a CSM, and assessment and measurement endpoints.

2.1 Site Description and Ecological Setting

A brief summary of the Site operations, physical setting, and remediation activities is presented below, followed by a description of the characteristics of the Site. ARCADIS (2009, 2003) and Geraghty & Miller (1996) present a more detailed discussion of Site history, geology, and hydrogeology. The Study Area for this SLERA is then defined, based on habitat characteristics and historical activities at the Site.

2.1.1 Operations History

A wood treating facility, owned by the American Creosoting Company, began operating at the Site in 1906. In 1961, the Indiana Creosoting Company, a subsidiary of the Monon Railroad, purchased the property. The Monon Railroad then merged with the Louisville and Nashville (L&N) Railroad in 1971, and wood treating operations were terminated later that year. The wood treating facilities and support infrastructure were subsequently razed and backfilled in 1976. L&N Railroad was the predecessor company to CSXT, who is the current owner of the property.

2.1.2 Physical Description

The Site currently covers approximately 33 acres along Clear Creek on the southern portion of Bloomington. The Site is presently bounded to the north by industrial/commercial and residential properties. Residential and light industrial properties are located to the west across the former rail line. Commercial property has been constructed east of the Site. The Site is bisected by Clear Creek which runs north-south through the center of the Site (Figure 2). The Site is also bisected by Country Club Drive which runs east-west through the center of the Site. The Site topography varies from 5 to 15 feet above the elevation of Clear Creek.

All structures were razed by 1976. The Site is currently unoccupied and overgrown with trees, shrubs, tall grasses and other vegetation. The only standing structure currently at the Site is a conex storage container with an adjacent drum storage area concrete pad on the northern parcel used by the environmental consultant. The Site is relatively flat, sloping near Clear Creek, and is covered by vegetation (brush and grasses), with a wooded corridor adjacent to Clear Creek.

The depth of first encountered groundwater at the Site ranges from approximately 3 to 5 feet below ground surface (bgs). The hydrogeology at the Site can be divided into two separate zones; the shallow unconsolidated material water bearing unit (surface to 2 feet into the top of the first bedrock unit) and the bedrock water bearing units (beneath the upper 2 feet of the first bedrock unit). The unconsolidated material potentiometric surface appears to be controlled by the flow of Clear Creek. Groundwater flow direction of the unconsolidated material has been shown to be in a southerly direction, similar to Clear Creek. Groundwater flows to the southeast and towards Clear Creek (ARCADIS 2009).

As previously mentioned, Clear Creek generally runs in a north-south direction bisecting the 39 acre Site (Figure 2). The banks on either side of the Study Area at Clear Creek slope to the water and are covered with herbaceous vegetation up to the water's edge. Photos of Clear Creek are provided in Appendix A. Surface drainage would be expected to enter Clear Creek. In fact, Clear Creek is the main drainage for a significant portion of the City of Bloomington and is prone to flash flooding. Further groundwater discharge into the creek is expected.

2.1.3 Investigation and Remediation Activities

The nature and extent of impacts at the Site continue to be investigated through ongoing investigation and remediation activities. All previous known environmental investigations/remediation efforts conducted at the Site are summarized in the Remediation Work Plan (ARCADIS 2009). Based on Site operational history, investigations have focused on DNAPL, SVOCs, VOCs, PAH components associated with creosote, and metals (arsenic and lead) which have been detected in soil and groundwater samples throughout the Site and in sediment and surface water samples from Clear Creek.

Onsite investigation activities include soil sampling and groundwater monitoring. Onsite remediation activities include: product disposal, removal of underground storage tanks (USTs) and associated dispenser pump piping systems, soil excavation and removal,

and manual DNAPL recovery and disposal. Onsite investigation and remediation is ongoing and therefore risk to human and ecological receptor from exposure to conditions onsite will be addressed in the final (remediation work plan) RWP.

Investigation activities related to the Study Area at Clear Creek include sediment, surface water and porewater sampling. Details of those sampling events and remediation efforts are provided below:

- In April 1991, Geraghty & Miller collected five sediment samples (SS-1, SS-2, SS-3, SS-4, and SS-5) from Clear Creek, downgradient of the Site. Samples were analyzed for SVOCs, VOCs, and selected total metals (arsenic, chromium, and copper).

- In August 2003, ARCADIS collected ten surface water samples (CS-1, CS-2, CS-3, CS-4, CS-5, CS-6, CS-7, CS-8, CS-9, and CS-10) from Clear Creek downgradient of the Site. Samples were analyzed for selected SVOCs (phenols, phthalates, and priority pollutant PAHs) and selected VOCs (benzene, toluene, ethylbenzene, and xylene [BTEX]). During this sampling event, disturbance of the creek bed associated with the sampling effort resulted in sheen generation at several locations. The surface water samples from these locations contained sheen material.

- In October 2003, ARCADIS collected eight surface sediment (SED-1, SED-2, SED-3, SED-4, SED-5, SED-6, SED-7, and SED-8) and eight surface water (SW-1, SW-2, SW-3, SW-4, SW-5, SW-6, SW-7, and SW-8) samples from Clear Creek, both upgradient and downgradient of the 2003 Site boundary (Figure 3). Sediment samples were collected from 0-6 inches bgs, because generally aquatic organisms do not contact subsurface sediment. Sediment samples were analyzed for SVOCs (including alkylated PAHs), BTEX, total metals, AVS / SEM (downgradient samples only), grain size, and total organic carbon (TOC). Sediment porewater was extracted from the downgradient sediment samples only and analyzed for dissolved metals and hardness. Surface water samples were analyzed for SVOCs (alkylated PAHs), BTEX, total metals, dissolved metals (downgradient samples only), and hardness. Water quality parameters were measured at each sampling location. Photographs of each sampling location are provided in Appendix A. Sampling log sheets and laboratory reports for the October 2003 sediment and surface water samples are included in Appendix B.

- The October 2003 sampling event was intended to provide representative data for the water column, whereas the August 2003 sampling event intentionally included sampling of sheen generated due to sampling-related disturbance of the creek bed.

- In an effort to mitigate potential DNAPL migration into Clear Creek, a creek liner and interceptor trench remediation system was designed and installed along an approximate 170 foot section of Clear Creek within the northern tract of the Site in the Summer/Fall of 2007. Details of permitting, general construction, and on-going operation and maintenance activities associated with the installation of the creek liner are provided in the Remediation Work Plan (ARCADIS 2009). In summary, the limestone creek bottom was excavated to a depth of approximately 2.0 ft below the original creek bed surface, along the reach of creek the liner to be installed. The excavation was then covered with the following layers: a gravel sub-base, a lower geotextile protective layer, a geomembrane liner (Seaman XR-5), an upper geotextile protective layer, stone bedding, a final geotextile mesh, and finally, the Armor Flex (concrete revetment system). A more detailed explanation of the liner installation project and complete as-built drawings detailing the exact specification and placement of materials associated with the creek liner will be provided to IDEM as a separate report.

- In September 2010, ARCADIS collected 15 sediment and surface water samples from Clear Creek (Figure 3). Twelve samples (SED/SW-09 through SED/SW-19 and SED/SW-23) were collected from within the Study Area while three samples (SED/SW-20 through SED/SW- 22) were obtained from upstream locations. Sediment samples from the top 6 inches were obtained using a hand core sediment sampler. Samples were analyzed for select SVOCs (phenols, phthalates, and priority pollutant and alkylated PAHs), and selected VOCs (BTEX). Sediment samples were also analyzed for grain size, TOC, and soot content. Surface water samples were also analyzed for hardness. Sampling logs and Laboratory reports are included as Appendix B.

2.1.4 Ecological Setting

The ecological setting for the Site has been defined through a BEA (ARCADIS 2003), wetland delineation studies (ARCADIS 2006), and several Site reconnaissance visits.

Baseline Ecological Assessment

A BEA for the western portion of the Site (Western Site) was completed by ARCADIS in 1995 and presented to IDEM in the Phase II Investigation Report in 2003 (ARCADIS 2003). The BEA was conducted in accordance with the available guidance at the time which was provided in Table C-1 of Appendix C of the 1996 IDEM VRP Guidance Manual. Consistent with guidance, the BEA included a desktop review of all relevant ecological and other studies conducted at the Site as well as a Site visit to determine the Site land use, surrounding land uses, Site ecology, presence of threatened or endangered species, and the presence or absence of ecologically susceptible areas.

During the BEA, information was obtained from existing maps and studies. In addition, the Indiana Department of Natural Resources (IDNR) Natural Heritage Data Center and the United States Fish and Wildlife Service (USFWS) were contacted to obtain information regarding threatened or endangered species that may potentially inhabit or frequent the Western Site or the surrounding ¼ mile area.

In addition to the desktop information review in 1995, two ARCADIS representatives completed a Site visit in May 1999. The Site visit was conducted to collect information on vegetation cover/land use, plant species composition of each cover type (e.g., herbaceous, shrub canopy), and wildlife presence or use of these areas. The Western Site, adjacent areas, and parts of Clear Creek were evaluated on foot. Much of the remaining ¼ mile was evaluated through a windshield survey.

The complete BEA and associated correspondence was submitted to the agency (ARCADIS 2003). The BEA identified Clear Creek as an ecologically susceptible area, requiring evaluation of potential risks.

Wetland Delineation Studies

In May of 2005 a wetlands delineation survey was completed on 17 acres of the Site (Western Site) by Davey Resource Group from Kent, Ohio. The survey identified four jurisdictional wetlands, totaling 1.586 acres, at the Site. The report was completed and submitted to ARCADIS on June 30, 2005. In August of 2006 an additional wetlands delineation survey was completed on the newly purchased 16 acres east of Clear Creek by Davey Resource Group. The two delineation survey reports were combined into a final Wetlands Delineation Report (Davey Resources 2006), and supplied in the *Further Site Investigation Report* (ARCADIS 2006) previously submitted to IDEM. The final wetland delineation report indicates that wetlands in the form of inundation or

saturated soils have formed on disturbed soils in areas that have been rutted and poorly graded. Ten wetlands totaling 5.253 acres are found within the Site area. The wetlands near the former operations areas were formed as a result of historical excavation activities associated with site remediation. .

Site Reconnaissance

As previously mentioned, Site reconnaissance was first conducted for the western half of the Site in 1999 in conjunction with the BEA. Additional observations of aquatic habitat characteristics were noted by ARCADIS representatives during sampling efforts in October 2003. More recently, two ARCADIS employees completed a Site visit in conjunction with sampling activities in Clear Creek. The Site, adjacent areas, and parts of Clear Creek were evaluated on foot. Much of the remaining ¼ mile surrounding the Site was evaluated through a windshield survey.

A description of Site ecology, as gleaned from the investigations described above, is supplied below.

2.1.4.1 Site Ecology

The following sections describe the general ecological characteristics of the Site, including soil and vegetation types, wetland locations, and aquatic and wildlife resources.

Soils

The *U.S. Department of Agriculture Soil Survey of Monroe County* (USDA 1981) was reviewed to determine the soil type(s) located at the Site. Soils at the Site are classified as loamy Udorthents. These soils are characterized as being nearly level to moderately sloping, deep, and somewhat poorly drained in disturbed areas.

Vegetation

As described above, the Site is vacant of all buildings except some small concrete slabs and other building debris. The majority of the Site is covered with grasses, weeds, and other herbaceous vegetation. However, several small, forested areas are present onsite. A five- to twenty-foot wide strip of trees extends along the entire eastern boundary of the Site along the western bank of Clear Creek. Dominant tree species include box elder (*Acer negundo*), sycamore (*Platanus occidentalis*), black

locust (*Robinia pseudo-acacia*), honeysuckle (*Lonicera sp.*), silver maple (*Acer saccharinum*), rose (*Rosa spp*.), and red bud (*Cercis canadensis*). Another forested area exists toward the northern edge of the Site. Dominant species in this area include willow (*Salix sp*.), honeysuckle (*Lonicera sp.*), maple leaf viburnum (*Viburnum acerifolium*), hackberry (*Celtis occidentalis)*, silver maple (*Acer saccharinum*), and sycamore (*Platanus occidentalis)*.

Within a ¼ mile of the Site, vegetated areas exist to the south and east. Forested areas are present to the south of the Site. The eastern bank of Clear Creek is also vegetated with herbaceous plants and trees; however, this area is spatially limited due to the presence of other commercial and industrial facilities.

Wetlands

Ten wetlands totaling 5.253 acres are found within the Site. The wetlands will be addressed at a later date, under the Army Corp of Engineers Nation Wide Permit #38 (approved in May 2010), since onsite investigation and remediation is in progress.

Aquatic Resources

The aquatic resources onsite are limited to the areas described above. Clear Creek bisects the Site (Figure 2). The banks on either side of the creek slope to the water and are covered with herbaceous vegetation up to the water's edge. Deciduous trees are also found along the banks of Clear Creek as described above. At the time of the initial Site visit in 1999, the water was approximately one to three feet deep and two feet below the bottom of the bank, likely the result of low water flow. Water levels were similar during the October 2003 and September 2010 investigation events. The average width of Clear Creek along the Site is 25 feet. Bedrock forms the underlying substrate of Clear Creek. Throughout a majority of the length of the creek adjacent to the Site, the bedrock is exposed, with very few depositional areas. Isolated sand bars are located at various points in Clear Creek. Small pieces of building debris and cement blocks were found at several locations throughout the creek. Evidence of beaver in the study area was observed in 1999, October 2003, and September 2010. Beyond the southern beaver dam, the water level in Clear Creek decreased significantly and was only several inches high in some areas. Photographs of Clear Creek are provided in Appendix A.

The overall physical quality of Clear Creek at several locations adjacent to the Site was assessed in October 2003 using the Qualitative Habitat Evaluation Index (QHEI),

developed by the Ohio Environmental Protection Agency (Rankin 1989), and consistent with the U.S. EPA's *Rapid Bioassessment Protocols for Use in Streams and Wadeable Rivers* (Barbour, Gerritsen 1999). Aquatic habitat was evaluated on numerous physical variables, such as substrate, in-stream cover, riparian zone, bank erosion, and pool and riffle quality. Scores developed from the QHEI indicate that the segment of Clear Creek adjacent to the Site is in fair to good condition. The bedrock/gravel substrate and the narrow riparian zone on either bank of the creek limit the value of the aquatic habitat and contributed to the lower QHEI scores.

As a relatively small stream, Clear Creek supports populations of smaller fish. In October 2003 and September 2010, small fish were observed throughout the length of the creek adjacent to the Site. IDEM monitors fish in the creek because of an unrelated polychlorinated biphenyl (PCB) source upstream of the Site. A group 5 fish consumption advisory is currently in place for PCB contamination in Clear Creek for all fish species. A fish consumption advisory for PCBs is also in place for Lower Salt Creek, potentially associated with contamination from Clear Creek in Monroe County and Pleasant Run Creek in Lawrence County.

Wildlife

Wildlife species observed during the various Site visits include cowbirds, blue jays, yellow warblers, and tadpoles. Frogs can be heard from the larger wetland area; however, no individuals have been seen. Raccoon tracks have been seen along the Creek banks. Wildlife habitat onsite is limited to the open grassy area, the few trees in the northern portion of the Site, and the area of trees bordering Clear Creek. However, due to the industrialized nature of the Site and the close proximity of residential and commercial areas to the north, west, and east, other wildlife that may use the Site are likely limited to backyard species such as American robin, European starling, house sparrow, raccoon, Norway rat, and house mouse. Site conditions and observations were essentially the same in 2010.

Within a ¼ mile of the Site, similar backyard species are likely to be found in the commercial, industrial, and residential areas. More suitable wildlife habitat may be located immediately bordering Clear Creek. Deer and/or deer tracks have been observed along Clear Creek near the southern portion of the CSXT property. A Rails-to-Trails public walk path is located adjacent on the western border of the CSXT property. This recreational area may also provide some wildlife habitat; however, frequent use by recreators will limit the value of this area to wildlife species. Conditions and observations in the vicinity of the Site were substantially the same in 2010.

2.1.4.2 Threatened and Endangered Species

As part of the identification of potentially exposed receptors, it is necessary to identify protected species that may be exposed to Site constituents. In 1999, as part of the BEA, both the Indiana Natural Heritage Data Center (INHDC) and the United States Fish and Wildlife Service (USFWS) in Bloomington, Indiana were contacted to obtain information on state listed plants and aquatic and terrestrial wildlife onsite or within ¼ mile of the Site. At that time, no Indiana listed threatened or endangered species or significant habitats were identified; however USFWS responded that the Site is within the range of both the Indiana bat and the bald eagle. Correspondence with the IDNR is attached in Appendix C.

A recent check of the USFWS online database (USFWS, 2010) for Monroe County, Indiana indicates that the Indiana bat (*Myotis sodalis*) is still listed as endangered while the bald eagle (*Haliaeetus leucocephalus*) and the Arctic peregrine Falcon (*Falco peregrinus tundrius*) are in recovery.

Indiana Bat

Information provided by USFWS (Appendix C) indicates that the Indiana bat has a known hibernaculum several miles west of Bloomington. In addition, USFWS reported that Indiana bats may use Clear Creek for foraging habitat in summer, since these bats primarily forage over wooded stream corridors. However, no surveys have been conducted in the area to confirm the presence of a summer colony.

First listed in 1967, the Indiana bat continues to be at risk from disturbance by cavers, researchers, vandals, and natural catastrophes (for example, freezing temperatures, flooding) during winter. Estimates indicate that only nine hibernacula house 85 percent of the population in winter (USFWS 1999). Although protection of the summer population is important, clearly protection for wintering bats is critical to the continued success of the species.

In summer, most females migrate from winter hibernacula to areas north to establish nursery colonies. These colonies are usually housed behind the loose bark of trees, including bitternut hickory, shagbark hickory, and green ash, near the northern part of the range (Humphrey, Richter et al. 1977; Kurta, King et al. 1993). Often the characteristics of the tree (exfoliating bark with space for bats to roost) are more important than the tree species (USFWS 1999). The Indiana bat appears to have a strong site attachment and records indicate that individuals will return to sites

continually over several years (Humphrey, Richter et al. 1977; USFWS 1999). Studies show that the Indiana bat may fly up to 1.5 miles to reach foraging habitat (USFWS 1999). To date, no summer roosts have been identified onsite or within ¼ mile of the Site.

2.1.4.3 Identification of Potentially Impacted Ecologically Susceptible Areas

Consistent with IDEM (2001) guidance, ecologically susceptible areas include surface waters (streams, lakes, or ponds), wetlands, riparian areas (stream banks), and forest areas. Clear Creek and forested and wetland areas along Clear Creek are located within a ¼ mile of the Site. In addition, a Rails-to-Trails path is located adjacent along the western border of the CSXT property. All of these areas are considered ecologically susceptible; however, the habitat value of these areas for wildlife is limited given the proximity of numerous industrial, commercial, and residential development.

Onsite investigation and remediation is ongoing and therefore this SLERA is focused on the Study Area defined by the portions of Clear Creek associated with the Site. The Study Area could be impacted by onsite conditions through potential migration of constituents from soil through storm water and from groundwater through discharge to Clear Creek. Sediment and surface water sampling in the Study Area indicates that migration of PAHs from either soil or groundwater has resulted in detectable concentrations of Site-related constituents in critical habitat. These constituents are also associated with motor vehicle traffic and are expected to be present in runoff from Country Club Road. The road is an on-going source of PAHs to both the Site and Clear Creek.

2.1.5 Study Definition

Based on the ecological setting as described above, the Study Area for this SLERA is defined based on:

- The presence of ecologically susceptible areas; and
- The potential for Site-related constituent contamination from Site activities.

This SLERA focuses on the Study Area defined by the portions of Clear Creek associated with the Site since onsite investigation and remediation is ongoing. Therefore, the Study Area for this SLERA includes Clear Creek between the northern and southern boundaries of the Site. This portion of Clear Creek is potentially affected

by Site-related constituents. A section of Clear Creek approximately 600 feet upgradient of the Site is also evaluated in this SLERA as a reference area. Samples collected from this upgradient area provide information about background constituent concentrations in Clear Creek that are unrelated to the Site. The Study Area used in this definitive SLERA is slightly larger than that used in the preliminary SLERA. Specifically, the Study Area was expanded to the south to the vicinity of monitoring well (MW) 37 due to the observance of a non-toxic fluorescing dye emerging at the creek bank/creek bottom contact, during a tracer study conducted at the Site.

2.2 Receptors of Interest

It is not feasible to complete risk calculations for all species potentially exposed. Such an effort would also be duplicative because of the similarity of exposure patterns among closely related species and those within like feeding guilds. For these reasons, receptors of interest (ROIs) are selected for quantitative risk assessment purposes. The selected receptors are representative of entire classes of organisms (that is, functional groups). Selection criteria for ROIs include sensitivity, exposure potential, likely presence in the Study Area, ecological relevance, trophic level, feeding habits, and the availability of life history information.

The aquatic ROIs evaluated in the SLERA are identified as entire biological communities (for example, benthic invertebrates). Aquatic-feeding wildlife are also included as ROIs in this SLERA to evaluate compounds that may potentially bioaccumulate in prey. The rationale for selecting each ROI is discussed below.

- Benthic macroinvertebrates – The benthic macroinvertebrate community lives in constant and direct contact with surface sediment that may be impacted by Site COCs. Invertebrates have vital functions within the ecosystem, including serving as a prey base for higher trophic level organisms and cycling of nutrients.

- Fish – The fish community lives in constant and direct contact with surface water that may be impacted by Site COCs. Exposures are also possible via sediment and the food chain, particularly for bioaccumulative constituents. The fish community often dominates perennial aquatic ecosystems, in terms of biomass, and fish serve as a prey base for piscivorous wildlife.

- Raccoon (*Procyon lotor*) – Raccoons represent the feeding guild of omnivorous mammals in aquatic systems. The raccoon has been reported to

be the most abundant and widespread medium-sized omnivore in North America (U.S. EPA 1993a) and has been observed onsite. Raccoons also tend to be more closely associated with aquatic systems than other mammalian omnivores, although they feed opportunistically from both aquatic and terrestrial sources. Exposures to raccoons are enhanced by relatively small territory sizes, as well as their potential to ingest sediment that may be attached to invertebrate prey.

- Belted kingfisher (*Ceryle alcyon*) – The belted kingfisher is selected to represent piscivorous birds in aquatic systems. Kingfishers may be found in shallow, open water alongside rivers, streams, lakes, and ponds (Hamas 1974, as cited in U.S. EPA 1993a). Exposure potential for kingfishers is enhanced by the high proportion of fish in their diet, limited territory sizes, and a comparatively high food ingestion rate relative to their body weight. Although kingfishers have not been observed in the Study Area, their assessment in this SLERA is conservative and protective of other bird species that may consume prey from the Clear Creek Study Area.

2.3 Constituents of Concern

The COCs that have been associated with the Site include: DNAPL (creosote), select SVOCs (phenols, phthalates, and priority pollutant and alkylated PAHs), BTEX, and metals (lead and arsenic specifically).

As described in Section 2.1.3, sediment, surface water, and porewater samples have been gathered from Clear Creek during four separate investigation events.

2.4 Exposure Pathways and Conceptual Site Model

Pathways by which ecological receptors may be exposed to Site COCs include absorption from water by gills, dermal uptake from water, dermal uptake from sediment, surface water ingestion, sediment ingestion, and ingestion of food (i.e., plant and animal tissue). For aquatic organisms, all exposure pathways are integrated by comparing sediment and surface water concentrations (as appropriate) to toxicological benchmarks for the respective exposure medium. For wildlife, doses obtained through ingestion of sediment, surface water, and food (estimated) are directly calculated and summed for comparison to toxicity benchmarks.

A CSM is a written description and visual representation of predicted relationships between ecological entities and the stressors to which they may be exposed. Figure 4 presents a graphical interpretation of the CSM for the Clear Creek area. As shown, the primary receiving media are sediment and surface water due to groundwater discharge from the Site. The sediment and water function as secondary sources of exposure to ecological receptors. Following uptake by aquatic organisms (i.e., benthic invertebrates and fish), biota tissue may function as a tertiary source of exposure to upper trophic level receptors (aquatic-feeding wildlife).

2.5 Assessment and Measurement Endpoints

Assessment endpoints are explicit expressions of the environmental value that is to be protected, operationally defined by an ecological entity (for example, fish, birds, mammals) and its attributes (for example, community structure, survival, growth, reproduction). Assessment endpoints are selected based on ecological relevance, susceptibility (which is a combination of toxicological sensitivity and potential for exposure), and relevance to management goals.

The following assessment endpoints are selected for Clear Creek:

- Benthic macroinvertebrate community structure and function;
- Survival and reproduction of fish communities;
- Survival and reproduction of aquatic-feeding mammal populations; and
- Survival and reproduction of piscivorous bird populations.

“Community structure and function” refers to the types and diversity of species present and their ecological roles (for example, serving as prey for wildlife). Community structure and function generally does not depend on the presence or absence of any single species. “Population” refers to a group of interbreeding individuals of a single species, occurring within a geographic area.

A measurement endpoint is defined as a measurable ecological characteristic that is related to the valued characteristic chosen as the assessment endpoint, and is a measure of biological effects. More than one measurement endpoint may be selected for a given assessment endpoint. For this definitive SLERA, measurement endpoints are simply defined as the comparison of measured constituent concentrations in

sediment or surface water to conservative ecological screening and background values and other relevant toxicological information.

3. Methods Used in the Screening Level Ecological Risk Assessment

The methods used in the SLERA are discussed in the sections below from data compilation to initial and refined screening and risk characterization.

3.1 Data Evaluation

Sediment and surface water data from the Clear Creek were compiled to support the screening-level exposure characterization. The data were reviewed for quality and then data tables for each media were prepared. Data were separated into two datasets: Upgradient Area data and Study Area (adjacent to Site) data. The Study Area datasets were then summarized. For each constituent detected at least once, the following summary statistics were identified: frequency of detection, minimum and maximum detected concentrations, minimum and maximum detection limit, and arithmetic mean. The data evaluation was conducted under the following assumptions and considerations.

- Quality assurance and quality control procedures were routinely used to evaluate analytical data quality. Analytical data from the laboratory were validated to evaluate the sample preservation and shipping methods, holding times, laboratory blanks, laboratory control samples, and matrix spikes.
- Sediment results were confirmed to be reported on a dry weight basis.
- Where there are duplicate results, the average detected concentration or the minimum detection limit for non-detected constituents was used. If a constituent was detected in a parent sample and not detected in the duplicate, the detected concentration was used.
- Non-detect values were very conservatively assumed to equal one-half the practical quantitation limit (reporting limit). The reporting limit is typically a factor of 4 to 5 higher than the method detection limit. Concentrations that lie between the reporting and detection limits are reported as estimated values, whereas non-detected concentrations are generally below the detection limit. Applying a proxy concentration to non-detect results that is higher than the method detection limit ensures that the true concentration is less than the proxy concentration.

- To facilitate risk estimation for wildlife, PAHs were separated into low (LPAH) and high (HPAH) molecular weight groups. The LPAHs (2- and 3-ring PAHs) included acenaphthene, acenaphthylene, anthracene, fluorene, naphthalene, phenanthrene, and 11 alkylated homologues of these PAHs. HPAHs (4-, 5-, and 6-ring PAHs) included benzo(a)anthracene, benzo(a)pyrene, benzo(b)fluoranthene, benzo(e)pyrene, benzo(g,h,i)perylene, benzo(k)fluoranthene, chrysene, dibenzo(a,h)anthracene, fluoranthene, indeno(1,2,3-cd)pyrene, perylene, pyrene, and five alkylated homologues of these PAHs. Total LPAH and HPAH concentrations were then calculated by summing the concentrations of LPAH and HPAH constituents for each sample, including both detected concentrations and one-half the reporting limit for non-detected constituents.

3.2 Screening-Level Exposure Characterization

The following sections provide a discussion of the screening level exposure characterization methods for benthic invertebrates, fish, and wildlife.

3.2.1 Benthic Invertebrates

Sediment and porewater data were used to characterize exposures to benthic invertebrates in this SLERA. Based on the relatively low mobility of benthic invertebrates, each sediment sample was treated as an exposure unit in this SLERA. The significance of risks associated with individual samples, if any, were evaluated on the magnitude and spatial extent of risks across the Study Area.

The exposure characterization for benthic invertebrates is described below for the classes of COCs at the Site.

3.2.1.1 Organics

The effects of organics on benthic invertebrates were assessed by evaluating sediment concentrations. However since the bioavailability of organics is affected by the amount of organic carbon in sediment and its type, TOC was also used in the evaluation. TOC in sediment was not analyzed in samples collected in 1991; however TOC was measured in sediment samples obtained in 2003 and 2010. Further, soot (black carbon [BC]) was also analyzed in the 2010 sediment samples.

PAHs

In evaluating exposure of benthic invertebrates to PAHs, the potential additive toxicological effects of PAHs were considered. PAHs are a large class of organic compounds that include unsubstituted compounds as well as those with alkyl, oxygen, or nitrogen substituents. For example, naphthalene is an unsubstituted (or "parent") PAH, and 2-methylnaphthalene is an alkylated PAH. Naphthalene compounds with a single methyl group, regardless of its position, are collectively referred to as C1-naphthalenes, while C2-naphthalenes have two methyl groups or one ethyl group, and C3-naphthalenes have three carbons attached to the parent ring structure (for example, three methyl groups).

Alkylated PAHs were not analyzed in sediment samples collected in 1991, therefore the full additive effects could not be properly characterized. However, sediment data from 2003 and 2010 was analyzed for both unsubstituted and alkylated PAHs, which enabled the evaluation of additive effects.

3.2.1.2 Metals

Sediment and porewater data were used to characterize exposures of benthic invertebrates to metals in this SLERA. The toxicity of metals in sediment is dependent on the bioavailable metal fraction. The bioavailable metal fraction in sediment is best described by the Equilibrium Partitioning (EqP) theory which relies on the premise that metals partition in sediment between sulfide, porewater, benthic organisms, and organic carbon (U.S. EPA 2005). In validating the EqP theory, it has been shown that the biological responses of benthic organisms to metals in sediments are different across sediments when the sediment concentrations are expressed on a dry weight basis, but similar when expressed on a SEM-AVS or interstitial water basis (U.S. EPA 2005).

Therefore, in this definitive SLERA, exposure of benthic invertebrates to metals in sediment was evaluated using porewater analysis, SEM-AVS analysis, and TOC analysis in addition to whole sediment metal concentrations. All these analysis were conducted on samples acquired in 2003.

3.2.2 Fish

Surface water concentrations were used to characterize exposures to aquatic organisms (fish) in this definitive SLERA. Because the Study Area is larger than the

home ranges of many fish, all measured concentrations of constituents in surface water were evaluated as exposure units. The spatial distribution of concentrations was examined to determine the significance of estimated risks, if any. Surface water data for organics and metals (total and dissolved) were obtained in 1991, 2003 and 2010.

The following sections provide a discussion of exposure assessment methods for fish for the classes of Site COCs.

3.2.2.1 Organics

The effect of organics on aquatic organisms (fish) was assessed by evaluating surface water concentrations.

PAHs

To evaluate the additive effects of PAHs to fish, both unsubstituted and alkylated PAHs were used in the assessment. Both unsubstituted and alkylated PAHs were analyzed in surface water samples collected in October 2003 and September 2010; however, only unsubstituted PAHs and 2-methylnapthalene (an alkylated PAH) were analyzed in samples from August 2003.

3.2.2.2 Metals

The evaluation of the effect of metals on fish relies on comparing surface water data to ecological criteria. The criteria for certain metals (barium, cadmium, lead, nickel, and zinc) are dependent on hardness. Therefore, site-specific hardness-dependent metals criteria were calculated using the average hardness measured.

3.2.3 Wildlife

The U.S. EPA (2000) has compiled a list of constituents that it considers to be potentially important bioaccumulative compounds. Constituents identified in the initial screening that have the potential to bioaccumulate according to the U.S. EPA are evaluated for aquatic-feeding wildlife in this definitive SLERA.

Exposure for wildlife receptors is determined by calculating the average daily intake of each potential bioaccumulative constituent, which integrates exposure via ingestion of sediment, surface water, and prey. Incidental sediment and surface water ingestion are estimated from measured constituent concentrations of each media within the

Study Area. Total metal concentrations are used for sediment and surface water exposures for wildlife in this definitive SLERA. Exposure concentrations in prey are estimated from site-specific sediment concentrations using biota-sediment accumulation factors (BSAFs). Wildlife exposure concentrations for sediment, surface water, and biota are then determined as the arithmetic mean of each constituent concentration in the Study Area. Mean values (and upper bound estimates of the mean) are appropriate for use in wildlife exposure assessment because exposure to wildlife does not really occur at any one fixed point; rather it occurs at a variety of points throughout the receptors' territories, with equal likelihood that any given point within the exposure unit will be the contact location on any given day.

3.3 Screening-Level Effects Characterization

This section describes the methods used to assess ecological effects. This assessment is implemented using a tiered approach. Initially, simple, highly conservative screening is used to eliminate many constituents from further evaluation. Constituents in sediment, porewater, and surface water that are not eliminated through the initial tier of the screening assessment are then evaluated further to determine whether they might pose a risk to ecological receptors. In some cases constituents are carried forward even if they pass the first tier of screening to evaluate cumulative effects. Effects characterization methods for the two tiers of the assessment are described below.

In the initial screening (Section 3.3.1), the maximum detected concentrations are compared with screening values. Use of the maximum concentration for exposure is intentionally conservative and will likely overestimate exposures to individual wildlife receptors and communities of benthic invertebrates and fish. In the second tier of screening, specialized techniques are used to refine the evaluation of the potential for adverse effects to benthic invertebrates, fish, and aquatic-feeding wildlife (Section 3.3.2). The methodologies used in both the initial and refined screening evaluations are discussed below.

3.3.1 Initial Screening

The initial screening-level effects assessment relied on conservative criteria and ecological screening values (ESVs) developed by IDEM and U.S. EPA, as well as site-specific background concentrations of naturally occurring metals. In the initial screening, maximum concentrations were compared to conservative ESVs and background levels. Constituents with maximum concentrations exceeding ESVs were identified as COPEC and carried forward in the assessment.

Data from the upgradient sampling locations are used to determine site-specific background concentrations of both organic compounds and metals; however, organic compounds are generally anthropogenic and are not screened out based solely on comparisons to background. The following sections discuss the initial screening per media.

3.3.1.1 Sediment

In the initial screening, maximum sediment concentrations were compared to sediment ESVs and to site-specific background concentrations if they were metals. Sediment ESVs are intended to be protective of aquatic life (including benthic organisms) and aquatic-feeding wildlife. IDEM has not adopted toxicity-based criteria or guidelines for constituents in sediment. Therefore, ESVs were identified from the U.S. EPA Region 5 Ecological Screening Levels (U.S. EPA 2003a). Where ESVs were not available from Region 5, attempts were made to obtain them from other sources such as U.S. EPA Region 3 Sediment Screening Benchmarks (U.S. EPA 2006); and U.S. EPA Region 4 Ecological Screening Values (U.S. EPA 2001). Finally, when ESVs could not be located for organics, equilibrium partitioning (EqP) sediment benchmarks (ESBs) were either directly obtained from the *Compendium of Tier 2 Values for Nonionic Organic Compounds* (U.S. EPA 2008) or calculated using methods in that guidance.

The standard approach to calculate ESBs for nonionic organic compounds (U.S. EPA 2008) uses the mass fraction of organic carbon in sediment (f_{oc}) and the constituent-specific partition coefficient between water and organic carbon (K_{oc}) to calculate sediment quality benchmarks using the water quality benchmark (WQB). The standard approach assumes that the bioavailable fraction of non-polar organic constituents is equivalent to the fraction of the sediment concentration that is freely dissolved in interstitial water, and that the freely dissolved fraction is determined primarily by the extent of partitioning to organic carbon. The standard ESB is calculated using this equation:

$$Standard\ ESB = WQB \times K_{oc} \times f_{oc}$$

This equation applies only to sediments having ≥ 0.2% total organic carbon by dry weight and nonionic organic chemicals with log K_{OW} ≥ 2 (U.S. EPA 2008).

The standard ESB equation (provided above) is ineffective for assessing less-hydrophobic organic compounds in sediment (like acetone), because it fails to account for the contribution of dissolved constituent to the total constituent concentration in sediment. For constituents having low K_{oc} values, this results in sediment quality

benchmarks that are more conservative than benchmarks calculated by assuming 100% bioavailability.

For less hydrophobic compounds (that is, compounds having log octanol-water partition coefficient (K_{ow}) values below 3.5), Fuchsman (2003) developed a modified ESB equation:

$$MESB = WQB \times \left[\left(f_{OC} \times K_{OC} \right) + \left(\frac{1 - f_{solids}}{f_{solids}} \right) \right]$$

Where:

MESB = Modified equilibrium partitioning sediment benchmark (mg/kg);

WQB = Water quality benchmark (mg/L);

f_{oc} = Fraction of sediment present as organic carbon (unitless);

K_{oc} = Organic-carbon/water partition coefficient (L/kg); and

f_{solids} = Fraction of sediment present as solids (unitless).

ESBs were calculated for organic compounds lacking screening values, using the equation above. Sample specific TOC values were used, where possible, otherwise the minimum TOC content reported onsite was used. K_{oc} values were obtained from U.S. EPA's EpiWin software (U.S. EPA 2010a). Where WQBs were not available, they were estimated using the U.S. EPA Ecological Structure Activity Relationships (ECOSAR) software (U.S. EPA 2009b). The EOCSAR program predicts the acute (short-term) toxicity and chronic (long-term or delayed) toxicity of a constituent to aquatic organisms such as fish, aquatic invertebrates, and aquatic plants by using Structure Activity Relationships (SARs).

3.3.1.2 Surface Water

For this definitive SLERA, the maximum detected concentrations of each constituent in surface water from the Study Area were compared to surface water ESVs for the protection of chronic aquatic life. Surface water ESVs were identified from those calculated by IDEM for selected substances using the Great Lakes Basin

methodologies (IDEM 2003). Where criteria were not available from IDEM, U.S. EPA Region 5 ESLs were used (U.S. EPA 2003a). Surface water ESVs are intended to represent minimum concentrations that might be of ecological concern with respect to aquatic life or aquatic-feeding wildlife.

For metals only, the maximum detected site-specific background concentrations were used as a secondary screening tool. Metals that exceed both the surface water ESVs and the site-specific background values were considered in the refined screening evaluation. Since the criteria for certain metals (barium, cadmium, lead, nickel, and zinc) are dependent on hardness, the average hardness for surface water samples within the Study Area was used to calculate hardness-dependent metals criteria.

3.3.1.3 Sediment Porewater

Concentrations of dissolved metals in porewater were compared in this definitive SLERA to the surface water ESVs, consistent with the EqP theory (U.S. EPA 2005). This approach provides more information about the bioavailability and potential toxicity of metals in sediment than the evaluation of total metal concentrations. However, it is subject to two significant sources of uncertainty (U.S. EPA 2005): (1) porewater extraction procedures such as centrifugation can result in an overestimation of the metal concentrations occurring in the porewater of undisturbed sediment; and (2) characteristics of porewater, such as elevated concentrations of dissolved organic carbon, can reduce the bioavailability of metals in porewater compared with water-only exposures. However, site-specific porewater OC was not measured or incorporated into the exposure calculations. These sources of uncertainty will tend to result in an overestimation of risks.

3.3.2 Refined Screening Evaluation

This section presents the methods used in the refinement of the initial screening evaluation. The refined screening evaluation focuses only on the COPECs and media that progress beyond the initial screening. The refined screening evaluation also considers specialized data (e.g., soot carbon and SEM & AVS data) and applies specialized toxicological techniques (e.g., evaluating mixtures and bioavailability) to further evaluate the potential for constituents to adversely affect aquatic organisms and aquatic-feeding wildlife in the Study Area. Effects characterization methods are described below for benthic invertebrates, fish, and wildlife.

3.3.2.1 Benthic Invertebrates

The refined evaluation for benthic invertebrates relies on cause-effect, concentration-response relationships for PAHs, other organic compounds, and metals in sediment and porewater, based on U.S. EPA guidance.

Sediment toxicity of a substance is related to the bioavailable fraction of that substance in the porewater of sediments. Substances that are sequestered by sediment ligands are neither bioavailable nor toxic to benthic organisms. It has been shown that both inorganics and organic compounds behave in that fashion. Organic compounds typically adhere to other organics in sediment such as humic acid. Inorganics can be sequestered by both organic matter in sediment and by sulfides present in the anoxic region of sediment.

Further, the toxicity of some constituents when present in mixtures can differ from when they are present alone. Toxicity of constituents in mixtures can be synergistic (1 + 1 > 2) or antagonistic (1 + 1 <2). U. S. EPA has issued guidance for evaluating metal mixtures and PAHs in sediment (U. S. EPA 2003b and 2005). These guidelines are applied in this definitive SLERA whenever a metal or a PAH constituent does not pass the initial screening evaluation.

Therefore, in the refined evaluation, both bioavailability and toxicity of mixtures were addressed. The following sections discuss how those issues were addressed per constituent class.

3.3.2.1.1 PAHs

PAHs occur as mixtures rather than individual constituents in the environment and because the toxicity of mixtures of narcotic constituents such as PAHs has been shown to be approximately additive, the assessment of PAHs should always consider the cumulative effects the various PAHs have when present in a mixture. The U.S. EPA (2003b) developed guidance for evaluating the toxicity of PAH mixtures in sediments which also considers their bioavailability: *Procedures for Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: PAH Mixtures.* The guidance presents final chronic values (FCVs) which are defensible, numerical, and constituent-specific concentration limits of PAHs applicable across a range of sediment types that can be used to assess the extent of ecological risks of contaminated sediments, determine pollution control, and identify, prioritize, and implement appropriate cleanup levels (U.S. EPA, 2003b).

To evaluate the combined toxic contributions of PAHs in a mixture, the sum of the quotients of the measured PAH concentrations (normalized to organic carbon) to the FCVs for each individual PAH is calculated. The quotient is called an Equilibrium Partitioning Sediment Benchmark Toxic Unit ($ESBTU_{FCV}$ or TU) and the summation as represented by $\Sigma ESBTU_{FCV}$ (total TU) is analogous to a hazard index (HI).

$$TU = \frac{[PAH_1]}{FCV_1} + \frac{[PAH_2]}{FCV_2} + \mathrm{K} + \frac{[PAH_n]}{FCV_n}$$

If the HI (total TUs) is equal to or less than one in a given sediment sample, the concentration of the PAH mixture in sediment is acceptable for the protection of benthic organisms. If the HQ exceeds one, the concentration of the PAH mixture in the sediment may not be acceptable for the protection of benthic organisms.

Where PAHs were COPECs in this SLERA, the ESBTU approach was used. Sample specific TOC was used. U.S. EPA's sediment quality guidelines are designed to be applied to a minimum of 34 PAHs, including alkylated PAHs. Default uncertainty factors (UFs) are typically used for the assessment of smaller subsets of the total PAH concentrations in the absence of site-specific data for alkylated PAHs (U.S. EPA 2003b), default uncertainty factors (UFs) are typically used for the assessment of smaller subsets of the total PAH concentration. However, no adjustment factor is needed for sediment in this definitive SLERA because both alkylated and parent PAHs were analyzed.

3.3.2.1.2 Metals

Like PAHs, the assessment of metals in sediment should consider both their bioavailablity and their cumulative effects when present in a mixture. The U.S. EPA (2005) developed guidance for evaluating the bioavailability and toxicity of mixtures of selected metals in sediments: *Procedures for Derivation of Equilibrium Partitioning Sediment Benchmarks (ESBs) for the Protection of Benthic Organisms: Metal Mixtures (Cadmium, Copper, Lead, Nickel, Silver, and Zinc) (U.S. EPA 2005)*. The effects of metals on benthic invertebrates were assessed by applying the U.S. EPA's metal mixture guidelines to the results of the whole sediment SEM-AVS analysis as parallel lines of evidence. Additionally, exposure to porewater was evaluated cumulatively for all detected metals.

Porewater

Exposure to metals in porewater was evaluated cumulatively to account for potential additive effects. Adverse effects are not expected if the sum of the dissolved interstitial water concentrations for each of the metals divided by its respective water quality criteria (WQC) is less than 1.0. This is accomplished through the following equation:

$$\sum IWBU = \frac{[Metal_1]}{WQC_1} + \frac{[Metal_2]}{WQC_2} + K + \frac{[Metal_n]}{WQC_n}$$

where:

IWBU = interstitial water benchmark unit;
[Metal] = dissolved metal concentration in porewater; and
WQC = surface water quality criterion.

The WQC used in this evaluation were final chronic values (FCV) or secondary chronic values (SCV) where FCV were not available. For metals whose toxicity is hardness dependent, sample specific water hardness was used to calculate the WQC. This approach is comparable to the methods used by USEPA in the Procedures for the Derivation of Equilibrium Partitioning Sediment Benchmarks (USEPA 2005) for assessing toxicity due to six divalent metals that are associated with binding to sulfides (i.e., cadmium, copper, lead, nickel, silver, and zinc).

Sediment

Exposure to the bioavailable fraction of divalent metals (i.e., cadmium, copper, lead, nickel and zinc) in sediment can also be evaluated using SEM-AVS data. This can be further refined by also accounting for the role of TOC as a secondary factor controlling the bioavailability of these metals, in sediments where SEM concentrations exceed the concentrations of AVS. This is accomplished through calculating the organic-carbon normalized concentration of "excess" metals ([SSEM-AVS]/f_{oc}). According to U.S. EPA 2005, Toxicity is not likely if [SSEM-AVS]/f_{oc} is less than 130 µmol per gram organic carbon (µmol/g_{OC}); but is expected with 90 percent confidence if (SSEM-AVS)/f_{oc} exceeds 3,000 µmol/g_{OC}. The likelihood of toxicity associated with intermediate values is uncertain. For the purposes of this SLERA, the effects benchmark for (SSEM-AVS)/f_{oc} is conservatively identified as 130 µmol/g_{OC}.

Although chromium does not form insoluble sulfide complexes, the likelihood of sediment toxicity due to chromium can also be predicted based on AVS data

(Boothman, Berry et al. 1999). The toxicity and bioavailability of chromium depend on whether it is present as trivalent or hexavalent chromium. Because AVS limits reduction and oxidation (redox) speciation of chromium (and vice versa), it can be concluded that if AVS is present, then hexavalent chromium is not present. Trivalent chromium is highly insoluble and relatively non-toxic, such that chromium toxicity is not expected in sediments that contain AVS (Boothman, Berry et al. 1999). All of the sediment samples analyzed from the Site contained detectable concentrations of AVS; therefore, chromium-related toxicity to benthic invertebrates is not expected.

In this SLERA, SEM-AVS data are considered for cadmium, copper, lead, nickel, and zinc. The interpretation of AVS and SEM analyses is not subject to the potential (conservative) biases described in Section 3.3.1.3, associated with porewater extraction and porewater composition. However, loss of AVS during sampling is a potential source of conservative bias. The results of AVS and SEM analyses are interpreted according to U.S. EPA (2005) guidelines for assessing the risk of sediment toxicity due to mixtures of cadmium, copper, lead, nickel, and zinc. These effects benchmarks for (SSEM-AVS)/f_{oc} are applied in the SLERA on a sample-by-sample basis.

3.3.2.2 Fish

As part of the derivation of sediment quality guidelines for PAHs, the U.S. EPA (2003b) developed aqueous FCVs for PAHs. These FCVs were applied to PAH mixtures in surface water using the same TU methodology described in Section 3.3.2.1.1 for PAHs in sediment. Surface water samples collected in August 2003 were not analyzed for alkylated PAHs; however, the conservative bias associated with the use of one-half the reporting limit as a proxy for non-detected concentrations more than offsets the TU contribution of alkylated PAHs. On this basis, TU values were calculated for surface water samples in this SLERA without employing an adjustment factor. This approach accounts for potential additive toxicity of multiple PAHs, based on direct exposure to PAHs in surface water. However, exposures via surface water may be less important than ingestion of prey containing PAHs, because PAHs are hydrophobic. A U.S. EPA-sponsored evaluation indicates that the equilibrium partitioning guidelines developed for the protection of benthic invertebrates are protective of fish as well (Linton, Giere et al. 2000).

3.3.2.3 Wildlife

Effects to wildlife from constituents in sediment and surface water, that did not pass the initial screening and are considered bioaccumulative, are evaluated through the identification and use of avian and mammalian toxicity reference values (TRVs).

4. Results of the Screening Level Ecological Risk Assessment

As described in Section 3, the screening-level risk evaluation is accomplished through a tiered process where simple, highly conservative comparisons with screening values (Section 3.3.1) are followed by a more refined evaluation (Section 3.3.2) where necessary. COPECs (if any) that merit further evaluation to fully characterize ecological risks are identified and discussed.

This section presents the results of the preliminary SLERA based on samples from 1991 and 2003 and then the results of the definitive SLERA based on samples obtained in 2010.

4.1 Preliminary SLERA

The preliminary SLERA was conducted using data obtained in 1991 and 2003.

4.1.1 Data

Sediment, surface water, and porewater samples obtained in 1991 and 2003 were used in the preliminary SLERA. Sampling log sheets and laboratory reports associated with those sampling efforts are included in Appendix B.

The sediment, surface water, and porewater data are presented in Tables 4.1-1 through 4.1-3. Data summaries are presented in 4.1-4 through 4.1-6 for sediment, surface water, and porewater, respectively. Grain size analysis is presented in Table 4.1-7.

4.1.2 Initial Screening

The initial tier of the screening evaluation for sediment, surface water, and sediment porewater is presented in Tables 4.1-8 through 4.1-10, respectively, and discussed by media below:

Sediment

Constituents in sediment that are not eliminated from consideration based on comparison of maximum detected concentration to ESVs are:

- PAHs;

§ Four metals (arsenic, cadmium, chromium, nickel); and

§ Three other organic compounds (bis(2-ethylhexyl)phthalate, 4-methylphenol, 2-butanone).

Surface water

Maximum detected concentrations of PAHs and metals in surface water were compared to surface water ESVs in the initial screening. In the October 2003 surface water samples, metals were analyzed as dissolved metals as well as total metals. Dissolved metal analyses have been shown to more accurately predict aquatic toxicity than total metals analyses, because they better reflect the metal concentrations that are bioavailable to aquatic organisms. For this reason, dissolved metal analyses provide the most appropriate means of assessing risks to aquatic organisms (Bergman and Dorward-King 1997; 1993b; 1995; Prothro 1993). However, both total and dissolved metals concentrations were conservatively used in the initial screening.

Constituents in surface water that are not eliminated from consideration based on comparison of maximum detected concentration to ESVs:

· PAHs.

Porewater

Maximum detected concentrations of metals in porewater were compared to surface water ESVs in the initial screening. Dissolved metals in sediment porewater did not exceed screening criteria. However, sediment porewater data are used as part of the refined screening evaluation for benthic invertebrates based on the identification of certain metals as COPECs from whole-sediment data and also to account for cumulative effects.

4.1.3 Refined Screening Evaluation

In the refined screening evaluation, constituents identified as COPECs in the initial screening are further evaluated based on site-specific information, specialized analyses, and other relevant toxicological information. Those constituents with the potential to cause adverse effects to ecological receptors (benthic invertebrates, fish, and wildlife) in the Study Area are then discussed below. Only constituents identified

by the U.S. EPA (2000) as bioaccumulative (PAHs, arsenic, cadmium, and nickel) are evaluated for their potential effects to aquatic-feeding wildlife.

4.1.3.1 Benthic Invertebrates

Potential adverse effects to benthic invertebrates from PAHs, metals, and other organic constituents in sediment and sediment porewater are evaluated in this section of the SLERA.

4.1.3.1.1 PAHs

PAHs were identified as sediment COPECs in the initial screen. As discussed in Section 3.3.2.1.1, the U.S. EPA EqP TU approach (U.S. EPA 2003b) for evaluating the bioavailability and toxicity of 34 PAHs present in mixtures in sediments was used in the refined screen to assess the effects of the PAHs on benthic communities. However, 35 PAHs were included because C1-naphthalenes were reported as 1-methylnaphthalene and 2-methylnaphthalene. On the other hand, several PAHs that did not pass the initial screening were not part of the 34 addressed by U.S. EPA guidance – namely: 1,1-Biphenyl, dibenzothiophene (unsubstituted and alkylated), carbazole, and dibenzofuran. All but dibenzofuran did not have identified ESVs. Therefore those PAHs were evaluated separately by comparison to calculated ESBs.

Dibenzofuran was detected in 7 out of 10 samples with a maximum of 3,100 µg/kg at SS-1 in 1991 which exceeded the ESV of 449 µg/kg. The second highest detected concentration of dibenzofuran was 330 µg/kg in sample SS-3 taken in 1991, while the maximum concentration detected in the 2003 samples was 79 µg/kg. The risk from dibenzofuran was refined using the EqP approach. The TOC in the sample with the maximum concentration was 0.55%, therefore the maximum concentration normalized to carbon content is 0.02 $\mu g/g_{oc}$, which is considerably lower than the Tier 2 ESB value of 37 $\mu g/g_{oc}$ (U.S. EPA 2008). Therefore, it was concluded that concentrations of dibenzofuran in Clear Creek are not expected to cause adverse effects to ecological receptors.

PAHs via U.S. EPA's Equilibrium Partitioning Toxic Unit Approach

The refined evaluation of PAHs in sediment, through the EqP TU approach, indicates that benthic organisms within the Study Area may be affected by PAHs (Table 4.1-11). Elevated PAH concentrations, within the Study Area, were observed at sampling locations near Country Club Road (SED-3, SS-1, and SS-3) and slightly upgradient of

Country Club Road (SED-4 and SS-4). Sheening from the bedrock substrate was observed at SED-3 and SS-1 sampling locations during both sampling events in 2003. Interestingly, PAH concentrations were also elevated in the upgradient reference area. In fact, the highest concentrations of PAHs determined from both the study and reference areas, and the highest TU calculated for the 2003 samples, were located at the sampling location the most upgradient of the Site (SED-8).

As discussed in Section 3, the toxicity of PAHs to benthic organisms is dependent on the amount of organic carbon in sediment. The levels of TOC in sediment samples from the Study Area (ranging from 0.55 to 1.36 percent) and the upstream reference area (ranging from 0.61 to 1.0 percent) are relatively low. The gravel/bedrock substrate of Clear Creek (see Table 4.1-7) contributes to the reduced organic carbon content in sediment samples. Material high in organic matter typically is associated with depositional areas, characterized by finer grained sediment than observed in the 1991 and 2003 samples. These are also the areas where PAHs and other hydrophobic constituents are likely to accumulate. The 2010 sampling event refined this uncertainty by focusing on finer depositional materials to the extent practical.

Further, the preliminary SLERA does not account for the enhanced affinity of PAHs for soot particles, which is recognized as a factor that can mitigate bioavailability and toxicity to benthic invertebrates (U.S. EPA 2003b). The presence of roads and industrial facilities upstream near Clear Creek suggest that soot has likely been deposited, together with PAHs, into the creek from combustion processes. As a result, the bioavailability of PAHs in Clear Creek using the 2003 sediment samples may be overestimated. Furthermore, TU values calculated for PAHs in 2003 sediment samples from within the Study Area only slightly exceed the effects threshold of 1.0 (i.e., 2), suggesting that any adverse effects would be limited to the most sensitive aquatic species.

Other PAHs

The following PAHs were also identified as COPECs in the preliminary SLERA: 1,1-Biphenyl, dibenzothiophene (unsubstituted and alkylated), carbazole, and dibenzofuran. All but dibenzofuran did not have identified ESVs. Therefore MESBs were calculated for those compounds using K_{oc} values obtained from U.S. EPA's EpiWin software (U.S. EPA 2010a) and the lowest chronic freshwater criteria estimated by ECOSAR (U.S. EPA 2009b). The TOC values in the sample with the maximum detected concentration of each PAH were used. Each of these COPECs is discussed separately below.

- 1,1-biphenyl: 1,1-biphenyl was detected in 3 out of 5 samples in the preliminary SLERA. The maximum detected concentration of 13 µg/kg of biphenyl was detected in SED-2 which had TOC measured at 0.55 % so that the maximum concentration normalized to carbon content is 5.64 µg/g_{oc}. Since the EqP Tier 2 ESB for 1,1-biphenyl is 37 µg/g_{oc}, which is much higher than the maximum concentration normalized to carbon content, it was concluded that concentrations of 1,1-biphenyl in Clear Creek are not expected to cause adverse effects on ecological receptors.

- Carbazole: carbazole was detected in 1 out of 5 samples in the preliminary SLERA with a maximum detected concentration of 200 µg/kg detected in SS-3 in 1991. An ESB was calculated using the Koc estimated by EpiWin (9160 L/kg), the minimum predicted chronic fresh water criteria identified by EOCSAR (1.015 mg/L for daphnids), and the minimum TOC measured (0.55%) for the Site. The calculated ESB of 51,000 µg/kg is much higher than the maximum detected concentration, therefore, it was concluded that detected concentrations of carbazole in Clear Creek are not expected to cause adverse effects to ecological receptors.

- Dibenzothiophenes: substituted dibenzothiophenes were detected in all 5 samples taken in 2003 with a maximum detected concentration of 130 µg/kg of C2-dibenzothiophene detected in SED-01, which had a TOC measured at 1.36%. An ESB was calculated using the Koc estimated by EpiWin (9160 L/kg), the minimum predicted chronic fresh water criteria identified by EOCSAR (0.140 mg/L for fish), and the minimum TOC measured in the 2003 samples (0.55%). The calculated ESB of 7,100 µg/kg is much higher than the maximum detected concentration, therefore, it was concluded that detected concentrations of dibenzothiophene in Clear Creek are not expected to cause adverse effects to ecological receptors.

4.1.3.1.2 Metals

While metals in surface water passed the initial screening, the following, metals were identified as sediment COPEC: arsenic, cadmium, chromium, and nickel. Therefore, the evaluation of metals in Clear Creek was refined using porewater data by the IWBU approach as presented in Table 4.1-12 and the sediment AVS-SEM data (Table 4.1-13). The analyses of metals in sediment porewater and AVS-SEM in sediment support the following observations:

- *Arsenic* – Arsenic is unlikely to cause adverse effects to benthic invertebrates. The maximum detected arsenic concentration in sediment porewater (2.8 µg/L) is well below the IDEM water quality criterion (148 µg/L). Furthermore, the cumulative effect of all metals detected in sediment porewater indicates that toxicity is unlikely, as the sum of IWBUs for all metals are below one.

- *Cadmium and nickel* – The AVS-SEM evaluation is inconclusive because the value of SSEM-AVS]/f_{oc}, for three of the five samples in the Study Area are associated with an indeterminate probability of toxicity, while that of two of the five samples indicated toxicity is unlikely (Table 4.1-13). However, the low concentrations of both cadmium and nickel in sediment porewater indicate that these metals pose no risk to benthic invertebrates. The concentrations of cadmium (0.2 µg/L) and nickel (5.1 µg/L) in sediment porewater are well below IDEM water quality criteria (6.5 and 149 µg/L, respectively). As described above, the cumulative evaluation of metals in porewater also indicates risk to benthic invertebrates is unlikely.

- *Chromium* – The maximum detected concentration of chromium in sediment porewater (1.7 µg/L) is well below the screening criteria determined by IDEM for trivalent chromium (238 µg/L). Cumulative toxicity due to metals is also unlikely, as described above.

In summary, the preliminary SLERA found that the toxicity to benthic invertebrates due to metals is very unlikely.

4.1.3.1.3 Other Organic Constituents

The organic constituents: bis(2-ethylhexyl)phthalate, 4-methylphenol, and 2-butanone are discussed below for their potential to cause adverse effects to benthic invertebrates.

- *Bis(2-ethylhexyl)phthalate* - Bis(2-ethylhexyl)phthalate, found in plastics, is ubiquitous in the environment and is a common laboratory contaminant. Bis(2-ethylhexyl)phthalate was detected in 2003 sediment samples at a maximum concentration of 1,300 µg/kg. In aqueous exposures, bis(2-ethylhexyl)phthalate is not toxic to aquatic organisms at concentrations up to the solubility limit (Call, Markee et al. 2001; Rhodes, Adams et al. 1995). Sediment spiked with 3,000,000 µg/kg bis(2-ethylhexyl)phthalate had no effect on either survival or growth of midges and amphipods (Call , Cox et al. 2001).

Based on these studies, bis(2-ethylhexyl)phthalate is very unlikely to adversely affect benthic organisms at the concentrations detected in Clear Creek.

§ *4-Methylphenol* - 4-Methylphenol is formed naturally as part of the biological degradation of woody organic matter and is also used industrially. 4-Methylphenol was detected in 2003 sediment samples at a maximum concentration of 830 µg/kg. The basis of the ESL of 20.2 µg/kg is unclear. A conservative, alternative screening value is thus calculated here for comparison, using the EqP approach as described in Section 3. A water quality benchmark of 530 µg/L is identified by using the U.S. EPA's (1993c) draft final chronic value for 2,4-dimethylphenol as a conservative surrogate, as it is well established that 2,4-dimethylphenol is more toxic than 4-methylphenol (e.g., Feng, Shuokui et al. 1996; Karabunarliev, Mekenyan et al. 1996; Schultz, Holcombe et al. 1986). The use of a well-understood surrogate compound is appropriate because relatively few studies have directly investigated the aquatic toxicity of 4-methylphenol. A K_{oc} of 106 is calculated for 4-methylphenol from the constituent specific log K_{ow} of 2.06. Together with a site-specific average organic carbon content of 0.86 percent and an average solids content of 77.9 percent, these values result in a sediment quality benchmark for 4-methylphenol of 630 µg/kg.

Because this value is below the maximum 4-methylphenol concentration reported in Clear Creek sediment samples used in the preliminary SLERA, 4-methylphenol might pose a risk to benthic invertebrates. However, this conclusion is highly uncertain, for several reasons. First, 4-methylphenol was detected only in 1991 and not in 2003, although the 2003 detection limits were well below the detected concentrations reported from 1991. Second, sample-specific organic carbon and solids data are not available for the 1991 sediment samples. Typically, organic compounds tend to be sequestered preferentially in sediments containing higher organic carbon levels; thus, the sample containing the maximum 4-methylphenol concentration may have contained a higher organic carbon concentration than assumed for this SLERA. Third, the use of 2,4-dimethylphenol as a surrogate to estimate 4-methylphenol toxicity is very conservative and overestimates risks. Fourth, 4-methylyphenol is non-ionic polar compound and EqP typically overestimate pore water concentrations for polar non-ionic compounds. Taken together, these considerations suggest that 4-methylphenol is relatively unlikely to adversely affect benthic invertebrates in the Study Area.

- *2-Butanone* - 2-Butanone, also called methyl ethyl ketone, is a common laboratory contaminant and may not actually occur in Clear Creek. 2-Butanone was detected in one 1991 sediment sample at a concentration of 880 µg/kg. The basis of the Region 5 ESL of 42.4 µg/kg is derived using EqP equation and corresponding water ESL. An alternative screening value was calculated here, using the EqP approach (U.S. EPA 2003), as described in Section 3, using the IDEM's water quality criterion of 14,000 µg/L, a K_{oc} of 1.8, and a site-specific average organic carbon content of 0.86 percent and an average solids content of 77.9 percent. The sediment quality benchmark for 2-butanone is calculated as 4,200 µg/kg. This value is well above the concentration reported in Clear Creek sediment (880 µg/kg), indicating that 2-butanone does not pose a risk to benthic invertebrates.

4.1.3.2 Fish

The evaluation of PAHs in surface water, using the modified TU approach, is provided in Table 4.1-14. The results of this evaluation differ markedly between the August 2003 and October 2003 sampling events. The August 2003 results indicate a high likelihood of toxicity between locations CS-5 and CS-9, whereas the October 2003 results indicate that toxicity is unlikely. This discrepancy reflects a difference in sampling methods between the two sampling events. The October 2003 sampling event was intended to provide representative data for the water column, whereas the August 2003 sampling event intentionally included sampling of surface sheen generated due to sampling-related disturbance of the creek bed. Exposure to sheen is minimal for aquatic organisms due to its presence at the water surface. Further, the October 2003 samples were analyzed for 35 PAHs while the August 2003 data was only analyzed for the non-alkylated PAHs, therefore the October data is associated with less uncertainty.

The results of the risk evaluation for benthic invertebrates exposed to PAHs in sediment are also of interest for fish, because fish may be exposed to PAHs through consumption of prey and direct exposure to sediment. The finding that benthic invertebrates may be at risk due to PAHs qualitatively implies that fish may also be at risk. However, the extent to which fish are exposed to sediment in Clear Creek is limited, because most of the creek bed consists of exposed bedrock with limited areas of coarse sediment. Thus, depositional sediments do not constitute an important reservoir of PAHs in this system. In summary, fish may encounter potentially toxic concentrations of PAHs on a spatially limited basis in the form of sheen or PAH-containing sediment, but direct toxicity due to PAHs in the water column is unlikely.

4.1.3.3 Wildlife

The following COCs did not pass the initial screening and were identified as potentially bioaccumulative: PAHs, arsenic, cadmium, chromium, and nickel.

Hexavalent chromium is identified by the U.S. EPA as a bioaccumulative compound; however, hexavalent chromium is not naturally occurring and is not expected to be present at the Site. Based on U.S. EPA research (Boothman, Berry et al. 1999), the presence of AVS in sediment indicates that chromium is present in the trivalent form. Since AVS was present in all sediment samples collected from the Study Area in October 2003, chromium within the Study Area is present in the trivalent form and therefore is not of concern with regard to bioaccumulation.

Therefore, the effects of PAHs, arsenic, cadmium, and nickel on aquatic-feeding wildlife were assessed in this SLERA. Ecological risks to wildlife are estimated through the calculation of hazard quotients (HQs). An HQ is the ratio of the measure of exposure to a literature-based TRV. An HQ less than or equal to 1 indicates that adverse effects due to a COC are unlikely. As shown in Appendix D, all HQs calculated for wildlife receptors in this SLERA are below 1, indicating that wildlife are not at risk due to COC exposures in the Study Area.

4.1.4 Results Summary and Outcome

The findings of the preliminary SLERA based on data acquired in 1991 and 2003 are summarized as follows:

- PAHs in sediment and sheen material are the only constituents that may pose a potential risk to aquatic organisms in Clear Creek based on slight exceedances of the target levels.

- Aquatic-feeding wildlife are not at risk from exposure to PAHs or other COCs in the Clear Creek Study Area. Risks unlikely even if surface sheen present, because contact with surface sheens is sporadic at most.

- Benthic invertebrates, and possibly fish, inhabiting the portion of Clear Creek upgradient of Country Club Road are at increased risk from PAHs. The source of PAHs in this area is unknown, but it is clear from these findings that multiple upgradient sources of PAHs are affecting the Study Area.

Based on the results of the preliminary SLERA, which was initially conducted in 2003, a creek liner and interceptor trench remediation system was designed and installed along an approximate 170 ft section of Clear Creek within the northern tract of the Site, immediately adjacent to the former operations area, in the Summer-Fall 2007. In September 2010, ARCADIS collected sediment and surface water samples to confirm the effectiveness of the mitigation measures taken. A definitive SLERA was conducted to evaluate the potential risk of adverse effects to ecological receptors from current conditions in Clear Creek. The definitive SLERA is presented below.

4.2 Definitive SLERA

The definitive SLERA is based on sediment and surface water data obtained in 2010. The definitive SLERA was conducted to evaluate the mitigation efforts conducted at a portion of Clear Creek near the former operations area and to evaluate the potential risk of adverse effects to ecological receptors from current (as of fall of 2010) conditions in Clear Creek.

4.2.1 Data

Sediment and surface water data obtained in 2010 were used in the definitive SLERA. Sampling log sheets, laboratory reports, and data validation reports associated with the 2010 sampling effort are included in Appendix B.

One of the contracted laboratories (Alpha Analytical) reported two sets of results for sample SED-14 and none for SED-12. To correct for the typographical mistake in transcribing the sample name, the results for SED-12 were identified based on the sample date and time rather than the sample name with the aid of the field log. Specifically, the sample with lab ID L1013935-13 was identified as being SED-12 since the sampling date and time (09/09/10 at 16:15) matched those of SED-12 per field notes.

Following data quality procedures for the project, a Tier II data validation was conducted by the ARCADIS internal data validation team. It was necessary to qualify a few compounds as unusable “R” as explained below.

- Sample location “SED-18” (8270C analysis), 2,4-dimethylphenol, due to both Matrix Spike/Matrix Spike Duplicate (MS/MSD) percent recovery <10%.

- Sample location “SED-14 (F76426-13)” (8270C analysis), all acid compounds due to surrogate percent recovery <10%.

Tables 4.2-1 and 4.2-2 present the analytical data obtained in 2010 for sediment and surface water, respectively, while Tables 4.2-3 and 4.2-4 present the 2010 Study Area data summaries for sediment and surface water, respectively.

4.2.2 Initial Screening

The initial tier of the screening evaluations for sediment and surface water are presented in Tables 4.2-5 and 4.2-6, respectively. Maximum detected constituent concentrations were compared with ecological screening values. The results of the screening are annotated below:

- BTEX, phthalates, and phenols were not detected in any of the sediment samples from Clear Creek; therefore, they were eliminated from further evaluation for sediment. Further, 4-methylphenol which was detected once in sediment samples from 1991 but not in 2003 was again not detected in any sediment samples in 2010.

- All phthalates analyzed with the exception of bis(2-ethylhexyl) phthalate were not detected in surface water and were thus eliminated from further evaluation in the SLERA.

- The only constituents considered COPECs at this point were PAHs in sediment and surface water and bis(2-ethylhexyl) phthalate in surface water.

4.2.3 Refined Screening Evaluation

In the refined screening evaluation, COPECs identified in the initial screening are further evaluated based on site-specific information, specialized analyses, and other relevant toxicological information. Those constituents with the potential to cause adverse effects to ecological receptors (benthic invertebrates, fish, and wildlife) in the Study Area are discussed below.

4.2.3.1 Benthic Invertebrates

PAHs were identified as sediment COPECs in the initial screen. As discussed in Section 3.3.2.1.1, the U.S. EPA EqP TU approach (U.S. EPA 2003b) for evaluating the

bioavailability and toxicity of 34 PAHs present in mixtures in sediments was used in the refined screen to assess the effects of the PAHs on the Clear Creek benthic community. Consistent with the preliminary SLERA, 35 PAHs were included because C1-naphthalenes were reported as 1-methylnaphthalene and 2-methylnaphthalene. Further, carbazole, which is a PAH that is not part of the 34 addressed by U.S. EPA guidance, did not pass the initial screening. Therefore, carbazole was also considered in the refined SLERA.

The evaluation of PAHs in sediment via the EqP TU approach indicates that benthic organisms within the Study Area are unlikely to be adversely affected by PAHs (Table 4.2-7). That is, the Sum TUs for each sediment sample was less than 1.0. Based on these results, the risks to benthic invertebrates associated with PAHs at Clear Creek appear to be negligible (i.e., *de minimis*) and do not warrant further evaluation.

Carbazole was detected in all samples collected in 2010 at concentrations ranging from 7.4 to 621 µg/kg. The maximum concentration was detected in sample SED-17 at 621 µg/kg (an average of 1210 and 33 µg/kg reported in duplicate samples at that location). The TOC content in SED-17 was 6.5%. An ESB was calculated using the Koc estimated by EpiWin (9160 L/kg), the minimum predicted chronic fresh water criteria identified by EOCSAR (1.015 mg/L for daphnids), and the minimum TOC measured at the Site (0.55%). The ESB of 51 mg/kg calculated using the lowest TOC content measured onsite (despite the fact that the TOC was an order of magnitude higher in sample with maximum concentration) is much higher than the maximum detected concentration. Therefore, it was concluded that detected concentrations of carbazole in Clear Creek are not expected to cause adverse effects on ecological receptors.

4.2.3.2 Fish

The evaluation of PAHs in surface water indicates that fish (and other aquatic biota) within the Study Area are unlikely to be affected by PAHs (Table 4.2-8). As with PAHs in sediment, the Sum TU for each surface water sample was less than 1.0. Based on these results, the risks to fish from PAHs in seep water discharging to Clear Creek appear to be negligible (i.e., *de minimis*) and do not warrant further evaluation.

4.2.4 Results Summary

The findings of the definitive SLERA are that significant adverse effects are unlikely at the aquatic habitat in Clear Creek that is associated with the Site.

5. Uncertainty Evaluation

Uncertainty can be introduced into a SLERA at every step in the evaluation process as information of varying quality is gathered from diverse sources in order to be integrated into a complex framework. The SLERA process is designed to be conservative, such that high confidence can be placed in findings of a lack of risk. Thus, where uncertainty exists, conservative assumptions are employed.

The uncertainties associated with key parameters and issues in this assessment are summarized below.

- Maximum concentrations – The use of maximum constituent concentrations is simplistic and highly conservative. Wildlife are actually exposed to a range of concentrations over time as they move throughout their foraging range.
- Screening values – The screening values selected for use in the initial screening tier of this SLERA are highly conservative.
- Aqueous FCVs for PAHs – These FCVs were derived using observed SARs based on the constituent's K_{ow} and general narcosis, rather than standard toxicity test data. Fish may be susceptible to effects other than general narcosis (Logan 2007), which could lead to the underestimation of potential risks. However, the FCVs used in this assessment were derived specifically for the PAHs in question and are based on a toxicity data set dominated by tests with water column biota, primarily fathead minnows. Also, use of the TU method quantitatively accounts for cumulative effects of all measured PAHs, which cannot otherwise be accomplished with the available toxicity data obtained from the literature.
- Photo-activation of PAHs – The toxicity of PAHs can be enhanced when organisms are simultaneously exposed to ultra violet (UV) light. In environments where significant sunlight penetrates to the sediment and benthic organisms are exposed to UV light, the EPA (2003a) screening values may be underprotective. Unfortunately, the likelihood and magnitude of potential phototoxicity cannot be accurately quantified at this time, due to the lack of *in situ* toxicity studies (Barron 2007). The water column in Clear Creek is shallow, but light penetration will be diminished by the typically turbid water in Clear Creek, which is depicted in the Site photos (Appendix A). However, organisms that are translucent to UV light and inhabit the water column or sediment surface are most at risk. Benthic organisms generally have low UV exposure because of morphological characteristics (e.g. sklerotized surfaces) and life history (Barron 2007).

- Soot carbon – Soot carbon, also called black carbon, has a much higher sorption capacity than biologically derived organic carbon (Ghosh 2007). PAHs may partition less to interstitial water in sediments with elevated soot carbon concentrations than predicted by the EqP model, thus making the sediment benchmarks overprotective (EPA 2003a). Although black carbon was measured in sediment collected at the Site, the potential reduction in estimated site-specific toxicity was not quantified, because it was deemed unnecessary since the sum of TUs using TOC alone was less than 1.0 for all samples.
- NAPL – As with soot carbon, NAPLs like coal tar may alter the sorption capacity of sediment, though the significance of these liquids relative to benthic toxicity is not yet fully understood (EPA 2003b). The sheen observed on the surface water in 2003 was a light NAPL, which is chemically very different from coal tar and unlikely to affect the bioavailability of PAHs in the same manner as such sediment-associated dense NAPLs. The sheen observed in 2010 was similar in quality to that observed previously, but was present in lesser quantity.
- Potential Cumulative effects of PCBs – The presence of additional nonionic narcotic constituents (e.g, PCBs) in the receiving environment, though unrelated to the Site, may make the EPA benchmarks for PAH mixtures underprotective, because the cumulative effect of multiple constituents with the same mode of action other than the measured PAHs is not accounted for by the sum of toxic units method (EPA 2003b). Fish consumption advisories are in place for Clear Creek in Monroe County due to elevated levels of PCBs in fish. This suggests that risks to fish and aquatic biota in the river may be greater than predicted in this assessment. This uncertainty is considered acceptable for this assessment, because the sum of toxic units is well below 1.0 for all 2010 water samples.
- Non-detected concentrations – As described in Section 3, a very conservative proxy value of one-half the reporting limit is used for non-detected constituent concentrations. This approach can significantly overestimate exposures.
- Bioaccumulation – In order to assess risks to aquatic-feeding wildlife, the bioaccumulation of PAHs in aquatic organisms was estimated from sediment data. Estimated concentrations in biota tissue are inherently more uncertain than measured concentrations. However, this source of uncertainty is of minor importance because none of the COPECs evaluated in this SLERA has the potential to biomagnify through the food web.

Due to the intentionally conservative nature of this SLERA, there would be greater uncertainty associated with findings of potential risk than with findings of a lack of risk.

However, the results for this assessment suggest that risks to all of the ecological receptors potentially exposed to PAHs in seep water discharging to Clear Creek are negligible (i.e., *de minimis*). Therefore, further evaluation to reduce these uncertainties is not warranted.

6. Summary and Conclusions

ARCADIS has developed this definitive SLERA on behalf of CSXT to assist with closure activities under the IDEM VRP at the former Indiana Creosoting Company facility. Due to ongoing investigation and remediation activities, this SLERA focused on the portion of Clear Creek that is associated with the Site as the Study Area.

The SLERA focused on the COCs at the Site which included DNAPL (creosote), selected SVOCs (phenols, phthalates, and priority pollutant and alkylated PAHs), and selected VOCs (benzene, toluene, ethylbenzene, and xylene [BTEX]), and metals (total, dissolved, and as SEM-AVS).

The SLERA was conducted in two phases. A preliminary SLERA was conducted in 2004 based on sediment, surface water and porewater data collected in 1991 and 2003. The preliminary SLERA concluded that the only COCs that may cause potential risk to ecological receptors in Clear Creek are PAHs in sediment. Based in part on the results of the preliminary SLERA, and intermittent presence of DNAPL globules on the creek bottom, a creek liner was installed along an approximate 170 foot section of Clear Creek within the northern tract of the Site, immediately adjacent to the former operations area, in the Summer-Fall of 2007.

Sediment and surface water samples were obtained from Clear Creek in 2010 to evaluate the effectiveness of the mitigation efforts. The data was used to conduct a definitive SLERA for the Study Area at Clear Creek. The results of the definitive SLERA indicate that ecologically significant adverse effects are unlikely at the Clear Creek Study Area due to Site related COCs. Therefore, further investigation of potential ecological risks and remediation to reduce potential ecological risks are not warranted for Clear Creek.

a. IDEM Water Quality Criteria were used preferentially. U.S. EPA Region 5 Resource Conservation and Recovery Act (RCRA) Ecological Screening Levels were used in the absence of IDEM criteria.
b. Values are maximum detected concentrations from upgradient surface water samples.
c. Screening for metals only based on exceedance of both the screening and background values.
d. Hardness-dependent metals criteria are calculated using the average study area hardness of 299 mg/L as $CaCO_3$.
e. Detected chromium concentrations do not exceed criteria for hexavalent chromium (shown above) or trivalent chromium (211 µg/L).

IDEM- Indiana Department of Environmental Management
NA - not available
ND - not detected
NM - not measured
µg/L - micrograms per liter

Total PAHs		7.67			34.10		
Total Toxic Units[b]				2			4

Notes:
2003 sediment data only.
Reference area includes: SED-6, SED-7, and SED-8.
Study area includes locations SED-1 through SED-5.

a. U.S. EPA 2003
b. A toxic unit value exceeding 1.0 indicates the potential for toxicity to benthic organisms.
* Average results for sample and duplicate used.

E - estimated value
mg/kg - milligrams per kilogram
PAHs - polycyclic aromatic hydrocarbons
U - not detected
µg/goc - micrograms per gram organic carbon

Table 4.1-12
Evaluation of Dissolved Metal Mixtures in Sediment Porewater - 2003 Data
Preliminary Screening Level Ecological Risk Assessment

a. Toxicity to benthic invertebrates is very unlikely at concentrations below 130 µg/goc and very likely at concentrations above 3,000 µg/goc. The likelihood of toxicity at intermediate concentrations in indeterminate.

AVS - acid volatile sulfide
moles/kg - moles per kilogram
SEM - simultaneously extracted metal
µmol/goc - micromoles per gram organic carbon
% - percent

Total Toxic Units[b]			0.4		1

Notes:
Upgradient area includes locations SW-6, SW-7, and SW-8.
Study area includes locations CS-1 through CS-10 and SW-1 through SW-5.

a. USEPA 2003
b. A toxic unit value exceeding 1.0 indicates the potential for toxicity to fish.
c. Detection limits not adequate to evaluate risks.
* Average results for sample and duplicate used.

J - estimated value
NM - not measured
U - not detected
µg/L - micrograms per liter

Water Quality (mg/L)									
Hardness		12/12	100	186	236	SW-18 *			203

* Sample has a duplicate. Result of parent and duplicate were set at: the average value or the detected value in case one was non-detect.

The results for duplicates were set as: the average value or the detected value in case one was non-detect.

For the arithmetic mean, one-half the detection limit was used for non-detects.

mg/l - milligrams per liter. ng/l - nanograms per liter. ug/l - micrograms per liter.

PAHs- polycyclic Aromatic Hydrocarbons

µg/kg- micrograms per kilogram

µg/goc- micrograms per gram organic carbon

Upgradient are included locations: SED -20, SED-21, SED-22.

[a] From USEPA 2003.

[b] A toxic unit value exceeding 1.0 indicates the potential for toxicity to benthic organisms.

* Average results for sample and duplicate used

Total Toxic Units [b]				0.3			0.2			0.2			0.3

PAHs - polycyclic aromatic hydrocarbons.
µg/L - micrograms per liter.
ng/L - nangrams per liter.
Upgradient area includes locations: SW-20, SW-21, SW-22.
[a]- From USEPA 2003.
[b]-A toxic unit value exceeding 1.0 indicates the potential for toxicity to benthic organisms.
* Average results for sample and duplicate used.

F76426-15	09/08/10	15:45	RD	09/09/10	SO	Soil	SED-15

Soil samples reported on a dry weight basis unless otherwise indicated on result page.

SAMPLE DELIVERY GROUP CASE NARRATIVE

Client: CSX Transportation **Job** F76426

Site: AGMININD: 9415829/ENV53216, Former Indiana Creosote Co, **Report Date:** 9/25/2010 10:23:09 AM

14 Samples and 1 Trip Blank were collected on 09/08/2010 and were received at Accutest SE on 09/09/2010 properly preserved, at 2.8 Deg. C and intact. These Samples received an Accutest job number of F76426. A listing of the Laboratory Sample ID, Client Sample ID and dates of collection are presented in the Results Summary Section of this report.

Except as noted below, all method specified calibrations and quality control performance criteria were met for this job. For more information, please refer to QC summary pages.

Volatiles by GCMS by Method SW846 8260B

Matrix: AQ **Batch ID:** VJ3338

All samples were analyzed within the recommended method holding time.

Samples F76356-1MS, F76356-1MSD were used as the QC samples indicated.

All method blanks for this batch meet method specific criteria.

Matrix: SO **Batch ID:** VG2525

All samples were analyzed within the recommended method holding time.

Samples F76376-6MS, F76376-6MSD were used as the QC samples indicated.

All method blanks for this batch meet method specific criteria.

F76426-9, F76426-11, F76426-15: Sample was received in a bulk container and preserved within 48 hours of sampling.

Matrix: SO **Batch ID:** VG2526

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76408-2MS, F76408-2MSD were used as the QC samples indicated.

F76426-13: Methanol extract analysis required due to matrix interference (non-target analytes present above calibration range). Sample was received in a bulk container and preserved within 48 hours of sampling.

Matrix: SO **Batch ID:** VK2009

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76266-37MS, F76266-37MSD were used as the QC samples indicated.

F76426-2, F76426-4, F76426-7: Sample was received in a bulk container and preserved within 48 hours of sampling.

Wet Chemistry by Method ASTM D422

Matrix: SO **Batch ID:** GN41406

Sample T58537-7BDUP was used as the QC sample for % Fines, % Gravel, % Sand.

Matrix: SO **Batch ID:** GN41439

Sample T58707-1BDUP was used as the QC sample for % Fines, % Gravel, % Sand.

Wet Chemistry by Method SM19 2540B M

Matrix: SO **Batch ID:** GN41317

Sample F76284-1DUP was used as the QC sample for Solids, Percent.

Saturday, September 25, 2010

Wet Chemistry by Method SW846 9060A MOD

Matrix: SO **Batch ID:** GP15611

All samples were prepped within the recommended method holding time.

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76426-9DUP, F76426-9MS were used as the QC samples for Total Organic Carbon.

Matrix Spike Recovery for Total Organic Carbon is outside control limits. Spike recovery indicates possible matrix interference and/or sample nonhomogeneity.

Accutest Laboratories Southeast (ALSE) certifies that this report meets the project requirements for analytical data produced for the samples as received at ALSE and as stated on the COC. ALSE certifies that the data meets the Data Quality Objectives for precision, accuracy and completeness as specified in the ALSE Quality Manual except as noted above. This report is to be used in its entirety. ALSE is not responsible for any assumptions of data quality if partial data packages are used.

SAMPLE DELIVERY GROUP CASE NARRATIVE

Client: CSX Transportation **Job** F76459

Site: AGMININD: 9415829/ENV53216, Former Indiana Creosote Co, **Report Date:** 9/28/2010 8:18:30 AM

18 Samples and 1 Trip Blank were collected on 09/09/2010 and were received at Accutest SE on 09/10/2010 properly preserved, at 2.6 Deg. C and intact. These Samples received an Accutest job number of F76459. A listing of the Laboratory Sample ID, Client Sample ID and dates of collection are presented in the Results Summary Section of this report.

Except as noted below, all method specified calibrations and quality control performance criteria were met for this job. For more information, please refer to QC summary pages.

Volatiles by GCMS by Method SW846 8260B

Matrix: AQ **Batch ID:** VB2907

All samples were analyzed within the recommended method holding time.

Samples F76427-6MS, F76427-6MSD were used as the QC samples indicated.

All method blanks for this batch meet method specific criteria.

Matrix Spike Duplicate Recoverys for Ethylbenzene, Toluene are outside control limits. Probable cause due to matrix interference.

RPD for MSD for Benzene is outside control limits for sample F76427-6MSD. Probable cause due to sample

Sample F76459-2MS has surrogates outside control limits. Probable cause due to matrix interference.

F76459-19: Sample vial(s) contained significant headspace; reported results are considered minimum values.

Matrix: AQ **Batch ID:** VC2933

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-12MS, F76459-12MSD were used as the QC samples indicated.

Matrix Spike Recovery for Ethylbenzene is outside control limits. Probable cause due to matrix interference.

Matrix Spike Duplicate Recoverys for Ethylbenzene, Xylene (total) are outside control limits. Probable cause due to matrix interference.

Sample F76459-2MS has surrogates outside control limits. Probable cause due to matrix interference.

Matrix: SO **Batch ID:** VH2414

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-3MS, F76459-3MSD were used as the QC samples indicated.

Sample F76459-2MS has surrogates outside control limits. Probable cause due to matrix interference.

F76459-3: Sample was received in a bulk container and preserved within 48 hours of sampling.

Matrix: SO **Batch ID:** VK2013

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-2MS, F76459-2MSD were used as the QC samples indicated.

Matrix Spike Duplicate Recoverys for Ethylbenzene, Xylene (total) are outside control limits. Probable cause due to matrix interference.

Sample F76459-2MS has surrogates outside control limits. Probable cause due to matrix interference.

F76459-1, F76459-2, F76459-4, F76459-5, F76459-6, F76459-7, F76459-8, F76459-9: Sample was received in a bulk container and preserved within 48 hours of sampling.

Wet Chemistry by Method ASTM D422

Matrix: SO **Batch ID:** GN41495

Sample F76459-3DUP was used as the QC sample for % Fines, % Gravel, % Sand.

Wet Chemistry by Method SM19 2540B M

Matrix: SO **Batch ID:** GN41323

Sample F76459-1DUP was used as the QC sample for Solids, Percent.

Wet Chemistry by Method SW846 9060A MOD

Matrix: SO **Batch ID:** GP15623

All samples were prepped within the recommended method holding time.

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-3DUP, F76459-3MS were used as the QC samples for Total Organic Carbon.

Matrix Spike Recovery for Total Organic Carbon is outside control limits. Spike recovery indicates possible matrix interference and/or sample nonhomogeneity.

Matrix: SO **Batch ID:** GP15631

All samples were prepped within the recommended method holding time.

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-6DUP, F76459-6MS were used as the QC samples for Total Organic Carbon.

Matrix Spike Recovery for Total Organic Carbon is outside control limits. Spike recovery indicates possible matrix interference and/or sample nonhomogeneity.

RPD for Duplicate for Total Organic Carbon is outside control limits for sample GP15631-D1. High RPD due to possible sample nonhomogeneity.

Matrix: SO **Batch ID:** GP15646

All samples were prepped within the recommended method holding time.

All samples were analyzed within the recommended method holding time.

All method blanks for this batch meet method specific criteria.

Samples F76459-8DUP, F76459-8MS were used as the QC samples for Total Organic Carbon.

Matrix Spike Recovery for Total Organic Carbon is outside control limits. Spike recovery indicates possible matrix interference and/or sample nonhomogeneity.

Accutest Laboratories Southeast (ALSE) certifies that this report meets the project requirements for analytical data produced for the samples as received at ALSE and as stated on the COC. ALSE certifies that the data meets the Data Quality Objectives for precision, accuracy and completeness as specified in the ALSE Quality Manual except as noted above. This report is to be used in its entirety. ALSE is not responsible for any assumptions of data quality if partial data packages are used.

Instrument Performance Check (BFB)

Job Number: F76459
Account: CSXT CSX Transportation
Project: AGMININD: 9415829/ENV53216, Former Indiana Creosote Co, Bloomington, IN

Sample: VK2013-BFB
Lab File ID: K046744.D
Instrument ID: GCMSK
Injection Date: 09/16/10
Injection Time: 12:28

m/e	Ion Abundance Criteria	Raw Abundance	% Relative Abundance		Pass/Fail
50	15.0 - 40.0% of mass 95	16015	26.3		Pass
75	30.0 - 60.0% of mass 95	34016	55.9		Pass
95	Base peak, 100% relative abundance	60849	100.0		Pass
96	5.0 - 9.0% of mass 95	4534	7.45		Pass
173	Less than 2.0% of mass 174	271	0.45	(0.65) [a]	Pass
174	50.0 - 100.0% of mass 95	41549	68.3		Pass
175	5.0 - 9.0% of mass 174	3177	5.22	(7.65) [a]	Pass
176	95.0 - 101.0% of mass 174	40132	66.0	(96.6) [a]	Pass
177	5.0 - 9.0% of mass 176	2855	4.69	(7.11) [b]	Pass

(a) Value is % of mass 174
(b) Value is % of mass 176

IS 1 = Fluorobenzene
IS 2 = Chlorobenzene-D5
IS 3 = 1,4-Dichlorobenzene-d4
IS 4 = Tert Butyl Alcohol-D10

(a) Upper Limit = + 100% of check standard area; Retention time + 0.5 minutes.
(b) Lower Limit = -50% of check standard area; Retention time -0.5 minutes.
(c) Sample was received in a bulk container and preserved within 48 hours of sampling.

* For NELAC purposes, Method 8260 includes analytes by SOP MS005 and Method 624 includes analytes by SOP MS003

Matrix: Designate "W" for Water, "S" for Soil, "O" for Oil, "Liq" for Non-aqueous Liquid, and "TCLP" or "SPLP" for Leachate

All strikeouts must be initialed and dated. If correction was not due to a transcription error, then list the reason for correction.

Manual Integration Rationale SOP QA029: **MP** Missed Peak, **OP** Overlapping Peak, **SP** Split Peak, **PDB** Poorly Defined Baseline, **BR** Baseline Ripple, **PII** Poor Instrument Integration

Report Date: 01/26/11

Case Narrative

The samples were received in accordance with the Chain of Custody and no significant deviations were encountered during the preparation or analysis unless otherwise noted. Sample Receipt, Container Information, and the Chain of Custody are located at the back of the report.

Results contained within this report relate only to the samples submitted under this Alpha Lab Number and meet all of the requirements of NELAC, for all NELAC accredited parameters. The data presented in this report is organized by parameter (i.e. VOC, SVOC, etc.). Sample specific Quality Control data (i.e. Surrogate Spike Recovery) is reported at the end of the target analyte list for each individual sample, followed by the Laboratory Batch Quality Control at the end of each parameter. If a sample was re-analyzed or re-extracted due to a required quality control corrective action and if both sets of data are reported, the Laboratory ID of the re-analysis or re-extraction is designated with an "R" or "RE", respectively. When multiple Batch Quality Control elements are reported (e.g. more than one LCS), the associated samples for each element are noted in the grey shaded header line of each data table. Any Laboratory Batch, Sample Specific % recovery or RPD value that is outside the listed Acceptance Criteria is bolded in the report. Definitions of all data qualifiers and acronyms used in this report are provided in the Glossary located at the back of the report.

Please see the associated ADEx data file for a comparison of laboratory reporting limits that were achieved with the regulatory Numerical Standards requested on the Chain of Custody.

For additional information, please contact Client Services at 800-624-9220.

Report Submission

This report replaces the one previously issued. The report was amended to change the client ID for sample L1013935-13 as requested.

Semi-Volatile Organics by 8270

The surrogate recoveries for L1013935-07, -08, -09, -11, -12 are outside the individual acceptance criteria for 2,4,6-Tribromophenol, but within the overall method allowances. The results of the original analysis are reported; however, all associated compounds are considered to have a potential bias.

Project Name: Not Specified
Project Number: Not Specified

Lab Number: L1013935
Report Date: 01/26/11

Case Narrative (continued)

The WG432076-3 LCS/LCSD RPD is above the acceptance criteria for Phenol (31%).

The WG433361-1 Method Blank associated with L1013935-01 through 06 has a concentration above the reporting limits for bis(2-Ethylhexyl)phthalate; however, this is within the method allowances for common laboratory contaminants. The associated samples are reported with a 'B' qualifier for any concentration less than 5 times that found in the method blank.

The WG433639-4/-5 MS/MSD recoveries, associated with L1013935-13, were below the acceptance criteria for 2-Methylphenol (MS 22.8%) and 2,4-Dimethylphenol (6.31%)/(3.76%); however, LCS results were within QC limits. In addition, the associated WG433639-5 MS/MSD RPD(s) are above the acceptance criteria for 2-Methylphenol (36%) and 2,4-Dimethylphenol (49%).

Alkylated PAH

The surrogate recovery for Method Blank WG432087-1 was outside the acceptance criteria for 2-Methylnaphthalene-d10 (42%); however, within the overall criteria. The results are reported with no qualification.

Total Metals

The WG433346-4 MSD recovery for Hardness (136%), performed on L1014191-14, is invalid because the sample concentration is greater than four times the spike amount added.

I, the undersigned, attest under the pains and penalties of perjury that, to the best of my knowledge and belief and based upon my personal inquiry of those responsible for providing the information contained in this analytical report, such information is accurate and complete. This certificate of analysis is not complete unless this page accompanies any and all pages of this report.
